18th October 2018

Interpretation-based

```
1 a ← input()
2 if (a > 0)
3   b ← a + 1
4 else
5   b ← a - 1
```

## Interpretation-based

```
1 a ← input()   [true]
2 if (a > 0)
3   b ← a + 1
4 else
5   b ← a - 1
```

Interpretation-based

```
1 a ← input()    [true]
2 if (a > 0)     [a > 0]
3   b ← a + 1
4 else
5   b ← a - 1
```

Interpretation-based

STATIC   DYNAMIC

```
1 a ← input()    [true]
2 if (a > 0)     [a > 0]
3   b ← a + 1
        [a > 0 ∧ b = a + 1]
4 else
5   b ← a - 1
```

Interpretation-based

SMT solver

yes/no extract

```
1 a ← input()    [true]
2 if (a > 0)     [a > 0]
3   b ← a + 1
        [a > 0 ∧ b = a + 1]
4 else
5   b ← a - 1
        [a ≤ 0 ∧ b = a - 1]
```

**Interpretation-based**

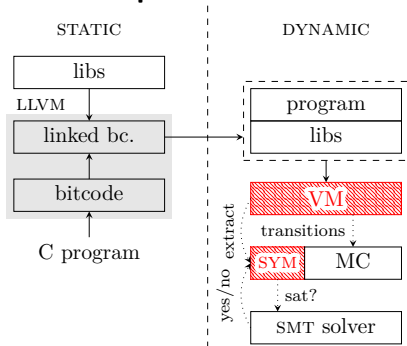

```
1 a ← input()    [true]
2 if (a > 0)     [a > 0]
3    b ← a + 1
         [a > 0 ∧ b = a + 1]
4 else
5    b ← a - 1
         [a ≤ 0 ∧ b = a - 1]
```

- multiple possible paths
- maintained in interpreter
- program does not know about symbolic values

Motivation: minimize complexity of the verification tool

Proposed Symbolic Computation
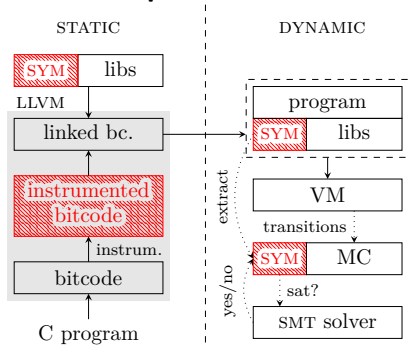

```
1 a ← input()
2 if (a > 0)
3   b ← a + 1
4 else
5   b ← a - 1

1 a ← sym_input()
2 if (sym_gt(a, 0))
3   b ← sym_add(a, 1)
4 else
5   b ← sym_sub(a, 1)
```

Motivation: minimize complexity of the verification tool

1 mixing of explicit and symbolic computation

1. mixing of explicit and symbolic computation
2. expose a small interface to the rest of the system

1. mixing of explicit and symbolic computation
2. expose a small interface to the rest of the system
3. impose minimal run-time overhead

Transformation

1 syntactically abstract the input program

```
x:int  ← input()          x: a_int  ← lift(*)
y:int  ← factorial(7)     y: int    ← factorial(7)
z:int  ← x + y            z: a_int  ← a_add(x, lift(y))
b:bool ← z < 0            b: a_bool ← a_lt(z, lift(0))
```

1 **syntactically abstract the input program**

```
x:int  ← input()            x: a_int  ← lift(*)
y:int  ← factorial(7)       y: int    ← factorial(7)
z:int  ← x + y              z: a_int  ← a_add(x, lift(y))
b:bool ← z < 0              b: a_bool ← a_lt(z, lift(0))
```

- transform instructions, types, functions
- preserve concrete computation
- lift concrete values

Transformation of Program

1 syntactically abstract the input program

```
x:int  ← input()            x: a_int  ← lift(*)
y:int  ← factorial(7)       y: int    ← factorial(7)
z:int  ← x + y              z: a_int  ← a_add(x, lift(y))
b:bool ← z < 0              b: a_bool ← a_lt(z, lift(0))
```

- transform instructions, types, functions
- preserve concrete computation
- lift concrete values

2 concretely realize abstraction

```
x: sym_int  ← lift(*)
y: int      ← factorial(7)
z: sym_int  ← sym_add(x, lift(y))
b: sym_bool ← sym_lt(z, lift(0))
```

- replace abstract calls with provided implementation

Problem: constrained values by control flow

```
x: int ← input()
cond: bool ← x < 0
if (cond)
  y: int ← x + 1
else
  ...
```

- both paths can happen
- x is not constrained

Control Flow of Symbolic Program

Problem: constrained values by control flow

```
x: int ← input()
cond: bool ← x < 0
if (cond)
  y: int ← x + 1
else
  ...
```

- both paths can happen
- x is not constrained

Solution: instrument constraint propagation

```
x: sym_int ← lift(*)
cond: sym_bool ← sym_lt(x, 0)
if (*) // nondeterministic
  x': sym_int ← assume(cond)
  y : sym_int ← sym_add(x', 1)
else
  x': sym_int ← assume(!cond)
  ...
```

- assumes extend a path condition

Problem: how to deal with aggregate types?

```
arr: int[]  ← [1, 2, 3]
arr[1]: int ← input()
```

■ we want to minimize the number of symbolic values

Problem: how to deal with aggregate types?

```
arr: int[]  ← [1, 2, 3]
arr[1]: int ← input()
```

- we want to minimize the number of symbolic values

Solution: use discriminated union type

- realize abstract value as union of *concrete* and *symbolic* value

```
arr: union[]  ← [1, 2, 3] // either int or sym_int
arr[1]: union ← lift(*)
```

- similarly deal with recursive structures

Problem: how to transform functions with symbolic arguments?

```
int foo(a: int, b: int, c: int)
```

Problem: how to transform functions with symbolic arguments?

```
int foo(a: int, b: int, c: int)
```

- may produce exponentially many duplicates:

```
int foo(a: sym_int, b: int, c: int)
int foo(a: int, b: sym_int, c: int)
int foo(a: int, b: int, c: sym_int)
int foo(a: sym_int, b: sym_int, c: int)
...
```

- resolve return type

Problem: how to transform functions with symbolic arguments?

```
int foo(a: int, b: int, c: int)
```

■ may produce exponentially many duplicates:

```
int foo(a: sym_int, b: int, c: int)
int foo(a: int, b: sym_int, c: int)
int foo(a: int, b: int, c: sym_int)
int foo(a: sym_int, b: sym_int, c: int)
...
```

■ resolve return type

**Solution**: static analysis + use discriminated union

```
union foo(a: union, b: union, c: int)
```

Symbolic Runtime

Data Representation

Symbolic execution:

```
a: pointer ← malloc()
w: sym_int ← lift(*)
x: sym_int ← lift(*)
y: sym_int ← sym_add(w, x)
z: sym_int ← sym_mul(y, 7)
store z → a
```
Data Representation

Symbolic execution:

```
a: pointer ← malloc()
w: sym_int ← lift(*)
x: sym_int ← lift(*)
y: sym_int ← sym_add(w, x)
z: sym_int ← sym_mul(y, 7)
store z → a
```

Branching example:

```
x : sym_int ← lift(*)
if (*) // nondeterministic
  x': sym_int ← assume(x < 10)
  y : sym_int ← sym_add(x', 1)
else
  x': sym_int ← assume(x >= 10)
  y : sym_int ← sym_sub(x', 1)
```

Cycle example:

```
x : sym_int ← lift(*)
for i: int ← 1 .. 2
  x: sym_int ← sym_add(x, 1)
```

Symbolic Verification Algorithm
Required support in a tool:

- nondeterminism
- feasibility check
- equality check
- values metadata

Simpler domains do not even need *SMT* support (sign domain).

Integrated with DIVINE model checker:

- LLVM-to-LLVM transformation
- STP SMT solver

Integrated with DIVINE model checker:

- LLVM-to-LLVM transformation
- STP SMT solver

Component sizes: (lines of code)

	DIVINE*	KLEE	SymDIVINE	CBMC
symbolic support	5.4	24.2	7	39.8
shared code	136.5	125	423	27.5

- reduced complexity of verification tool

Goals

1. mixing of explicit and symbolic computation ✓
2. expose a small interface to the rest of the system ✓
3. impose minimal run-time overhead ✓

Goals

1. mixing of explicit and symbolic computation ✓
2. expose a small interface to the rest of the system ✓
3. impose minimal run-time overhead ✓

Summary

- introduced compilation-based symbolic verification
- generalized approach to the abstraction of programs
